If there was only one scientific practice I could teach to every scientist regardless of stage or field I think it would be: look at the data. Spot check it. Find a few data points and trace them through to see if they make sense. Look at the raw data. Don't just do analyses.

According to this graph by @jean_twenge, college students were less in favor of free speech in 2019 than in any previous year. The peak of free speech was in the 1970s and 80s. It has been all downhill since the late 1980s, when political correctness first arose.

I bambini sono l'anello più debole in questa spirale di guerra. Save the children diffonde un numero straziante: oltre 10.000 sono stati uccisi in quasi 100 giorni. Ma a questa macabra contabilità manca un dato ed è quello dei bambini scomparsi, almeno 4.000

Today our comprehensive review of the social determinants of #mentalhealth was published in @WPA_Psychiatry World Psychiatry. Our piece reviews the current evidence on causes & prevention, & makes 7 recommendations framed around social justice.

- 1. Make social justice central to all public mental health interventions:** Mental health problems are inequitably distributed between and within populations, principally arising from systemic structural inequalities. Making social justice core to all public mental health interventions and policies would reduce these inequities
- 2. Invest in interventions that pay off in multiple domains:** Few social determinants solely affect mental health. Investing in interventions that target key social determinants will improve physical, mental and social outcomes for individuals and communities. Intervention programs should routinely measure mental health alongside these other outcomes
- 3. Invest in interventions that target critical windows of the life course to interrupt intergenerational transmission of mental health inequalities:** Half of all mental disorders start by age 18, leading to multi-domain problems over the life course. Early life and childhood adversities are both risk factors for, and consequence of such experiences. Minimising exposure to these adversities should be prioritised to interrupt this intergenerational transmission
- 4. Prioritise interventions that focus on poverty alleviation:** Any comprehensive public health approach to reduce the burden of poor mental health must include efforts to reduce poverty. Poverty is inextricably linked to most social determinants of mental health, and could be considered a root cause
- 5. Strengthen causal inference in social determinants of mental health and prevention research:** Most research on social determinants of mental health is observational, often subject to severe selection and confounding bias. Stronger causal inference methods are needed, as well as larger, interdisciplinary observational and experimental studies in representative and adequately powered studies to accelerate knowledge and develop effective primary interventions
- 6. Establish inclusive longitudinal population mental health monitoring:** Many countries struggle to accurately estimate psychiatric morbidity in their populations, inhibiting both clinical and public mental health provision. Samples are often unrepresentative. Reliable, inclusive and precise longitudinal monitoring of population mental health is the essential basis for effective prevention
- 7. Ensure parity between primary, secondary and tertiary prevention in mental health:** Investing sufficiently in primary prevention to stop the onset of mental disorders prevents suffering, improves quality of life, societal outcomes, and reduces demand for secondary and tertiary prevention

Bisogna complimentarsi per l'efficace preveggenza dei nostri decisori nazionali e locali, per la tempestività della loro prevenzione, per la grande campagna informativa e vaccinale, per il rafforzamento del nostro SSN, in particolare dei pronto soccorso, bravi bravi bravi

@WRicciardi | Walter Ricciardi | 4.01.2024

According to the latest CDC COVID-19 wastewater data, we are currently in the second-biggest surge of the pandemic. It will peak in the next week, with ~2 million infections per day. During this surge, ~100 million people total (~1 in 3 people in the US) will likely get COVID.
